### **Section A1: Procedure of principal component factor analyses**

We generated the outcome variables, the arithmetic mean indices of the division of routine and non-routine housework, by running factor analyses and rescaling the factors, so they conform to principal component analysis (PCA) (*Mooi et al.* 2018). We employed Stata's factor, pcf command to run the PCA. The analyses extracted two principal component factor scores, with an eigenvalue larger than 1 following the Kaiser criterion. The first factor included the four items "Preparing daily meals", "Vacuum cleaning the house", "Cleaning and mopping", and "Doing the laundry", which we interpreted as "routine housework". The second factor included the two items "Doing small repairs in and around the house" and "Paying bills and keeping financial records", which we subsumed under "non-routine housework". A third factor consisted of the single item "Organising joint social activities" that could not be assigned to a certain type of routine tasks (for similar results, see *Coltrane* 2000). We therefore excluded this item before generating both arithmetic mean indices.
